Modelling Interactions and Behaviour

Dr. Mohammed Ayoub Alaoui Mhamdi
Bishop's University
Sherbrooke, Qc, Canada
malaoui@ubishops.ca

Interaction Diagrams

- Interaction diagrams are used to model the dynamic aspects of a software system
  - They help you to visualize how the system runs.
  - An interaction diagram is often built from a use case and a class diagram.
    - The objective is to show how a set of objects accomplish the required interactions with an actor.

Interactions and messages

- Interaction diagrams show how a set of actors and objects communicate with each other to perform:
  - The steps of a use case, or
  - The steps of some other piece of functionality.
- The set of steps, taken together, is called an *interaction*.
- Interaction diagrams can show several different types of communication.
  - E.g. method calls, messages send over the network
  - These are all referred to as *messages*.

Elements found in interaction diagrams

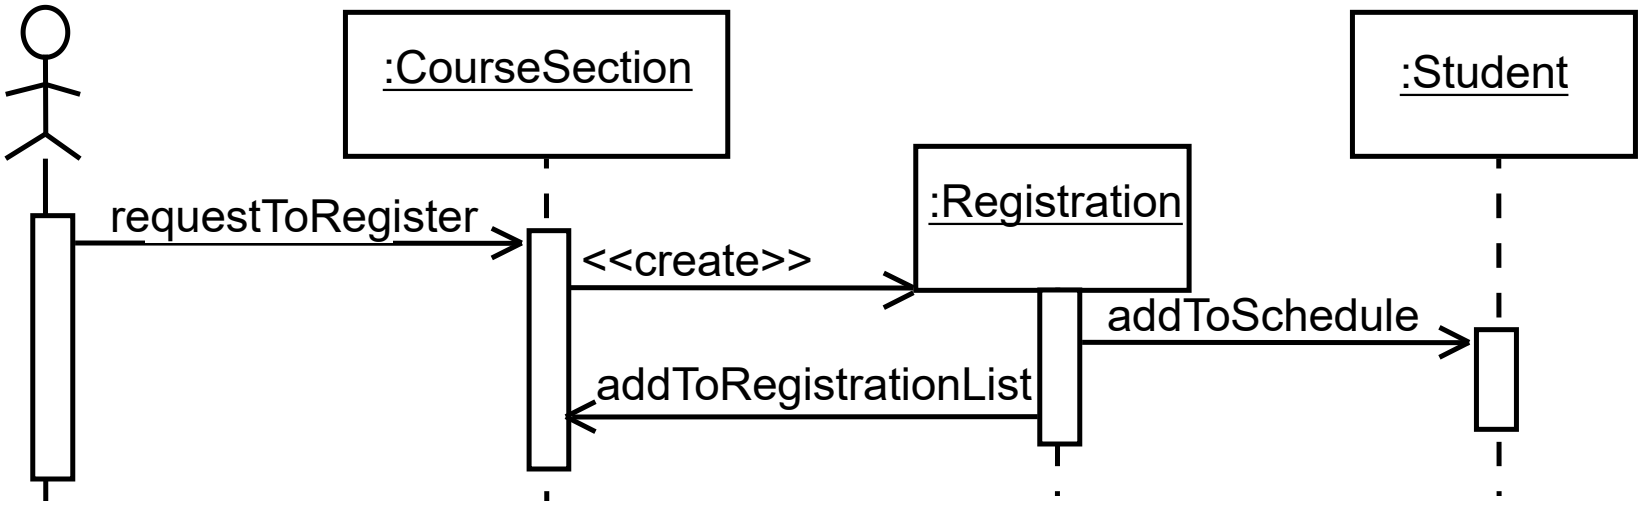
- Instances of classes
  - Shown as boxes with the class and object identifier underlined
- Actors
  - Use the stick-person symbol as in use case diagrams
- Messages
  - Shown as arrows from actor to object, or from object to object

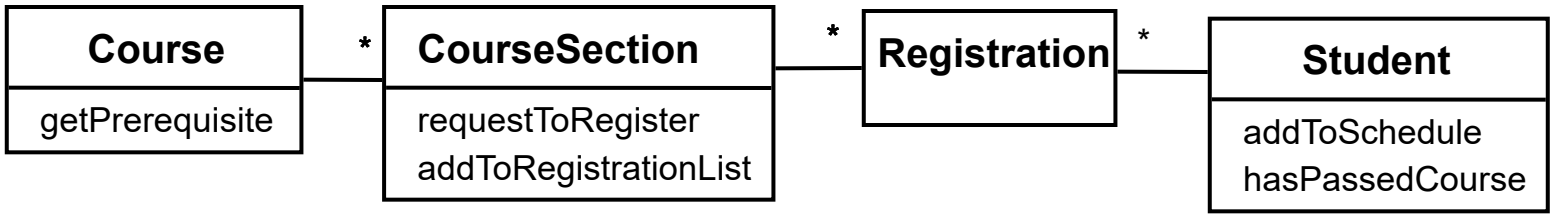
Creating instances diagrams

- You should develop a class diagram and a use case model before starting to create an interaction diagram.

- There are two kinds of interaction diagrams:
  - *Sequence diagrams*
  - *Collaboration diagrams*

Sequence diagrams – an example

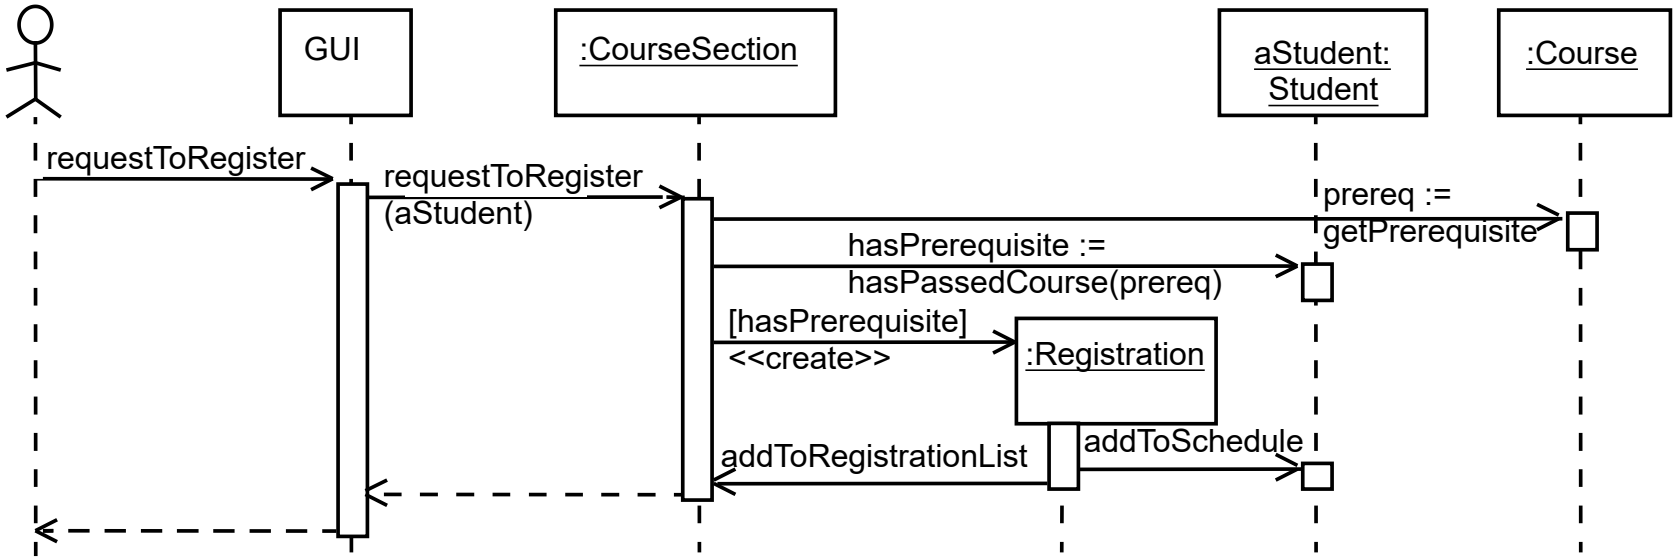




Sequence diagrams

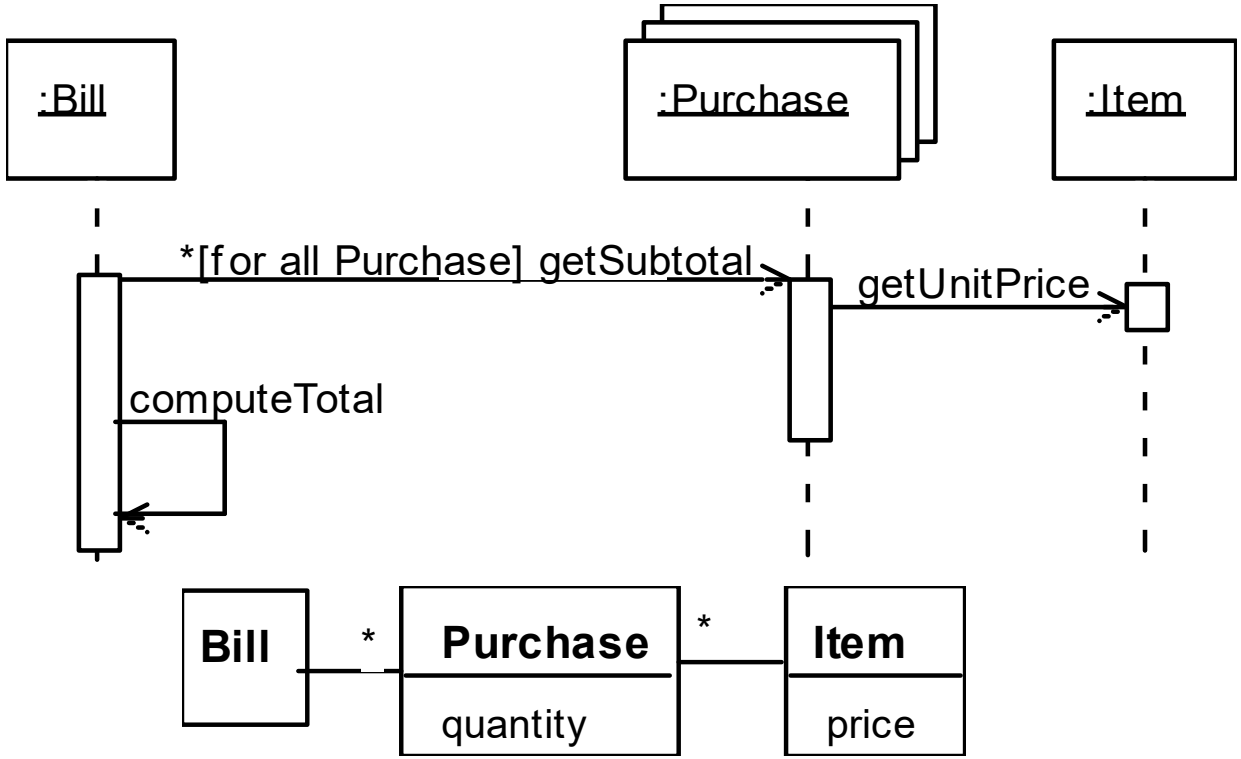
- A sequence diagram shows the sequence of messages exchanged by the set of objects performing a certain task
  - The objects are arranged horizontally across the diagram.
  - An actor that initiates the interaction is often shown on the left.
  - The vertical dimension represents time.
  - A vertical line, called a *lifeline*, is attached to each object or actor.
  - The lifeline becomes a broad box, called an *activation box* during the *live activation* period.
  - A message is represented as an arrow between activation boxes of the sender and receiver.
    - A message is labelled and can have an argument list and a return value.

Sequence diagrams – same example, more details



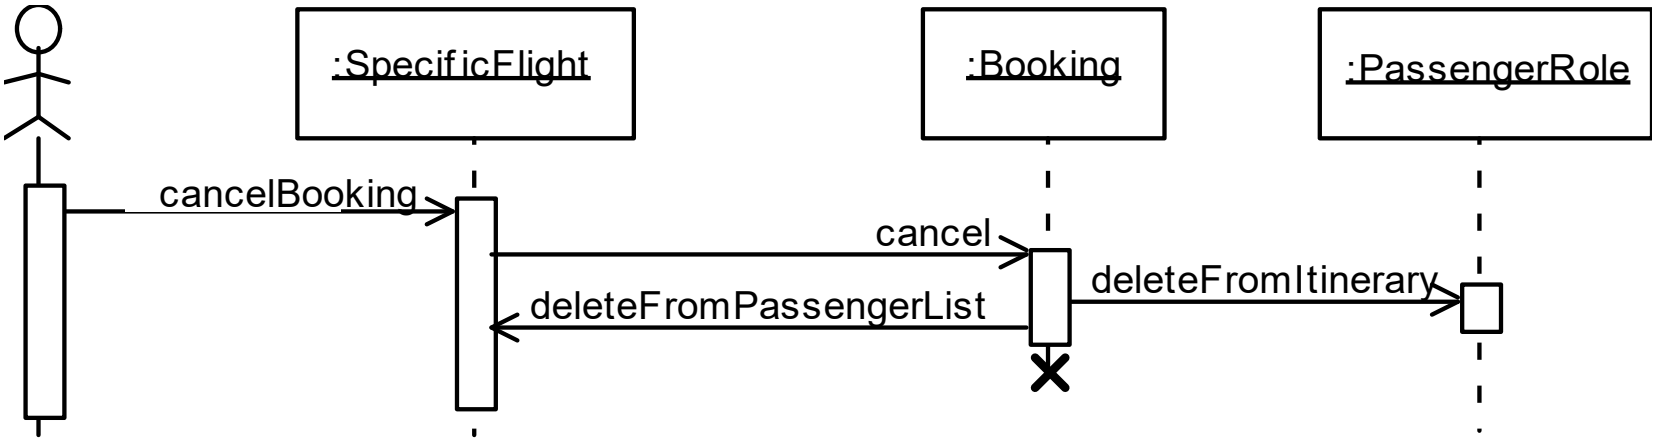
Sequence diagrams an example with replicated messages

- An *iteration* over objects is indicated by an asterisk preceding the message name



an example with object deletion

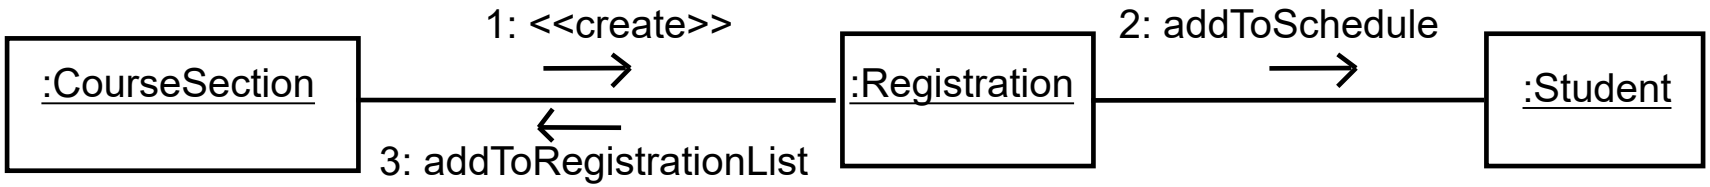
- If an object's life ends, this is shown with an X at the end of the lifeline



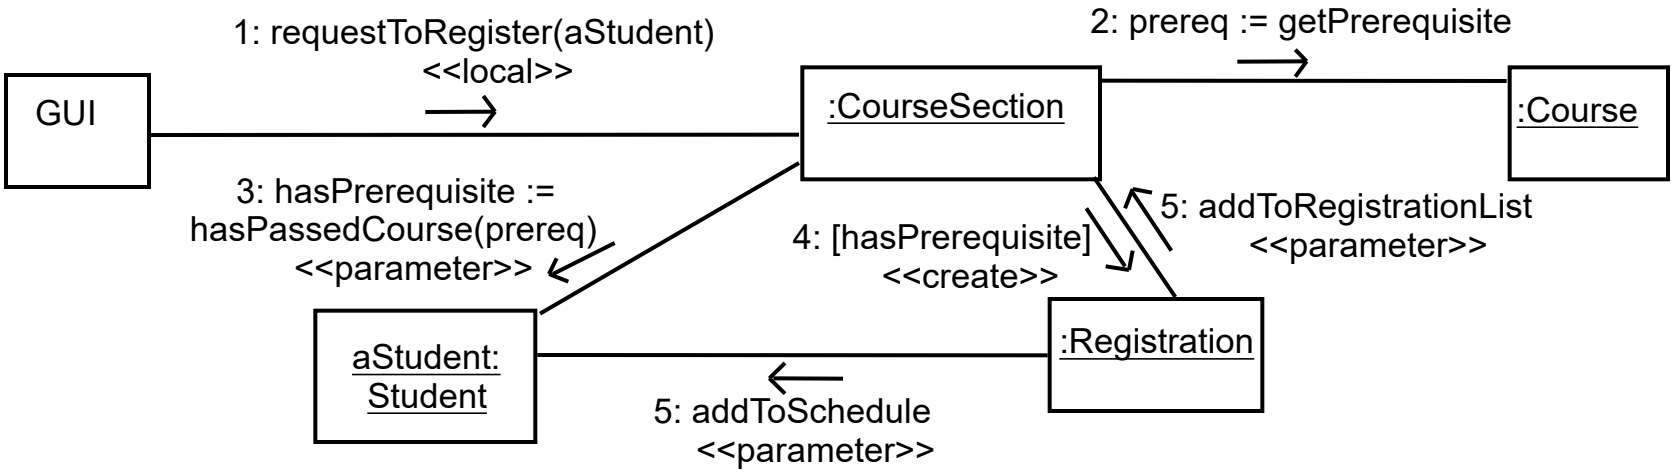
Collaboration diagrams

- Collaboration diagrams emphasise how the objects collaborate in order to realize an interaction
  - A collaboration diagram is a graph with the objects as the vertices.
  - Communication links are added between objects
  - Messages are attached to these links.
    - Shown as arrows labelled with the message name
  - Time ordering is indicated by prefixing the message with some numbering scheme.

Collaboration diagrams – an example



Collaboration diagrams – same example, more details



Communication links

- A communication link can exist between two objects whenever it is possible for one object to send a message to the other one.

- Several situations can make this message exchange possible:

1. The classes of the two objects have an *association* between them.
   - This is the most common case.
   - If all messages are sent in the same direction, then probably the association can be made unidirectional.

Other communication links

2. The receiving object is stored in a *local* variable of the sending method.
   - This often happens when the object is created in the sending method or when some computation returns an object .
   - The stereotype to be used is «local» or [L].

3. A reference to the receiving object has been received as a *parameter* of the sending method.
   - The stereotype is «parameter» or [P].

Other communication links

4. The receiving object is global.
   - This is the case when a reference to an object can be obtained using a static method.
   - The stereotype «global», or a [G] symbol is used in this case.

5. The objects communicate over a network.
   - We suggest to write «network».

sequence or collaboration diagram

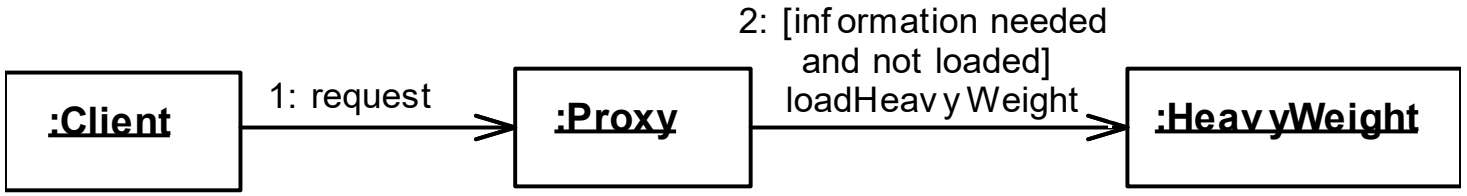
- Sequence diagrams
  - Make explicit the time ordering of the interaction.
    - Use cases make time ordering explicit too
    - So sequence diagrams are a natural choice when you build an interaction model from a use case.
  - Make it easy to add details to messages.
    - Collaboration diagrams have less space for this

sequence or collaboration diagram

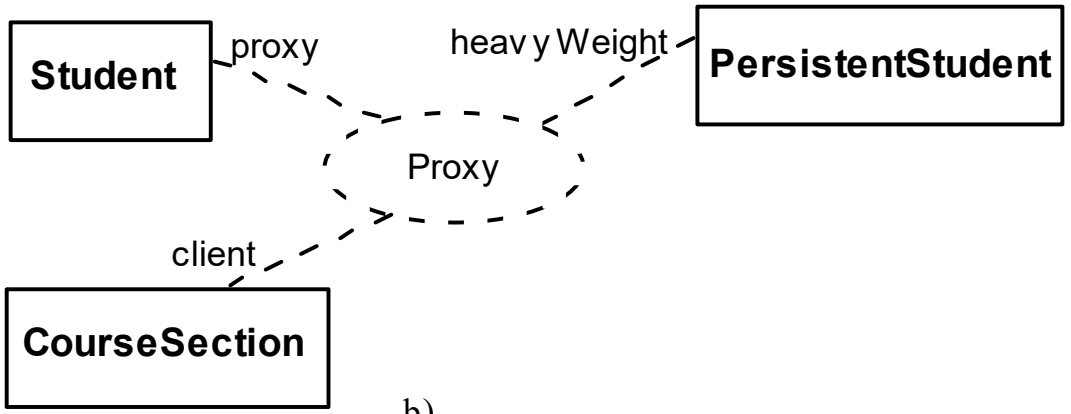
- Collaboration diagrams
  - Can be seen as a projection of the class diagram
    - Might be preferred when you are *deriving* an interaction diagram from a class diagram.
    - Are also useful for *validating* class diagrams.

Collaboration diagrams and patterns

- A collaboration diagram can be used to represent aspects of a *design pattern*



a)



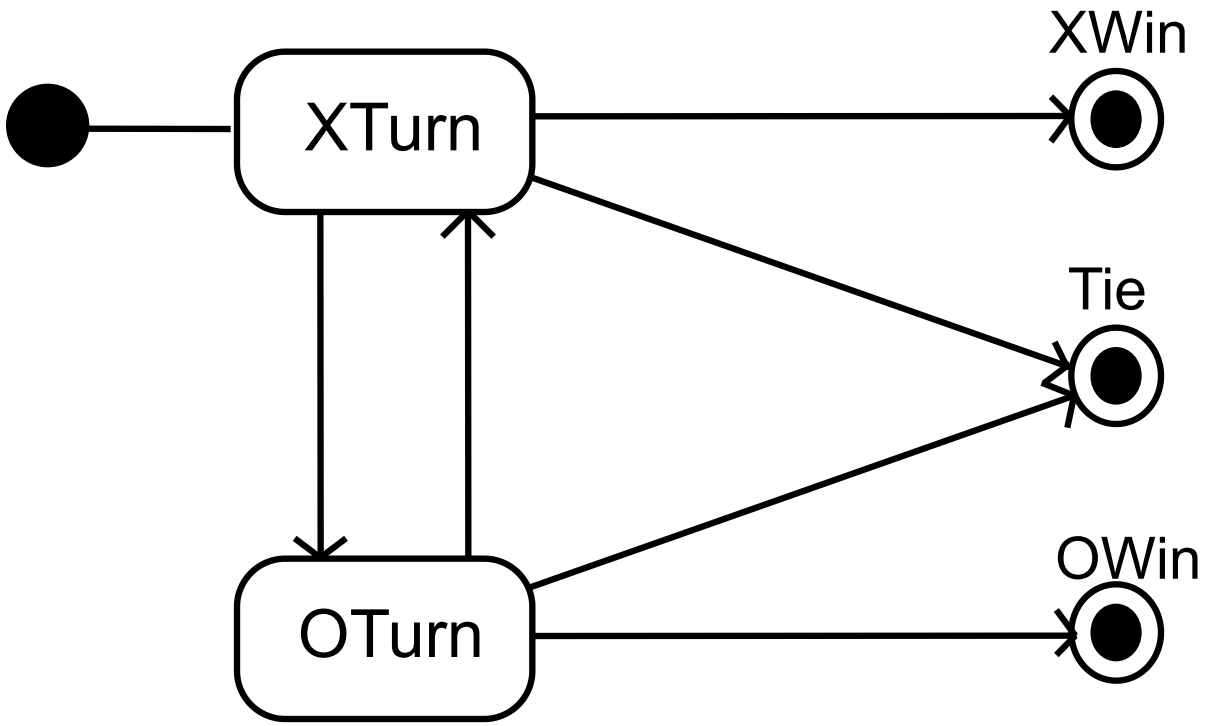
b)

State Diagrams

- A state diagram describes the behaviour of a *system*, some *part* of a system, or an *individual object*.
  - At any given point in time, the system or object is in a certain state.
    - Being in a state means that it is will behave in a *specific way* in response to any events that occur.
  - Some events will cause the system to change state.
    - In the new state, the system will behave in a different way to events.
  - A state diagram is a directed graph where the nodes are states and the arcs are transitions.

State diagrams - an example

- tic-tac-toe game



States

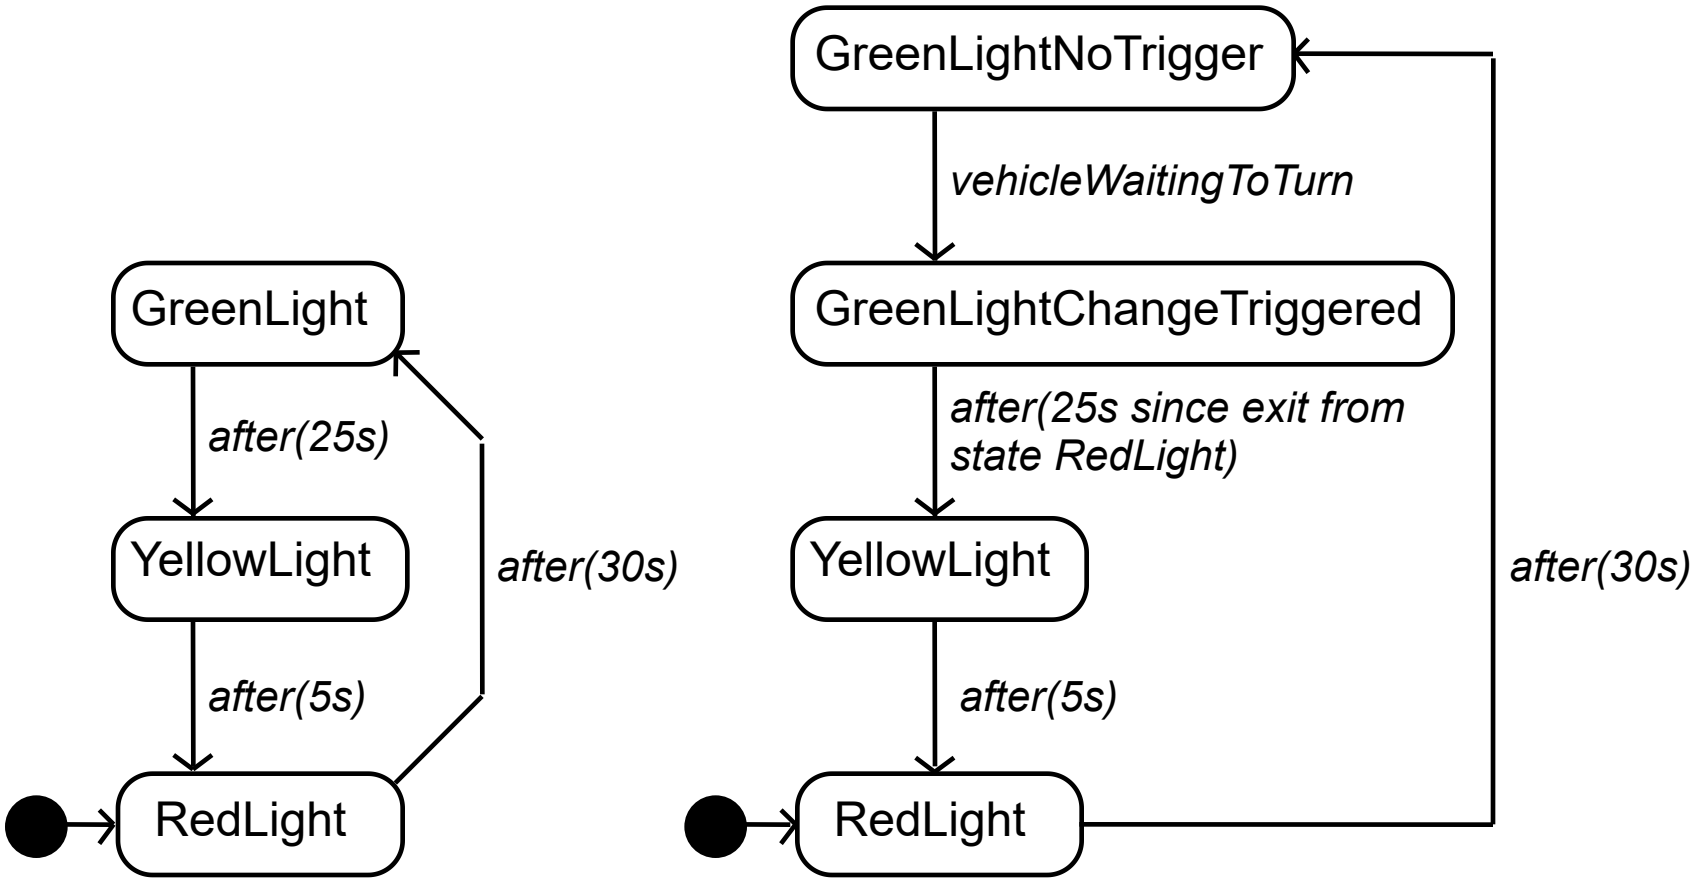
- At any given point in time, the system is in one state.
- It will remain in this state until an event occurs that causes it to change state.
- A state is represented by a rounded rectangle containing the name of the state.
- Special states:
  - A black circle represents the *start state*
  - A circle with a ring around it represents an *end state*

Transitions

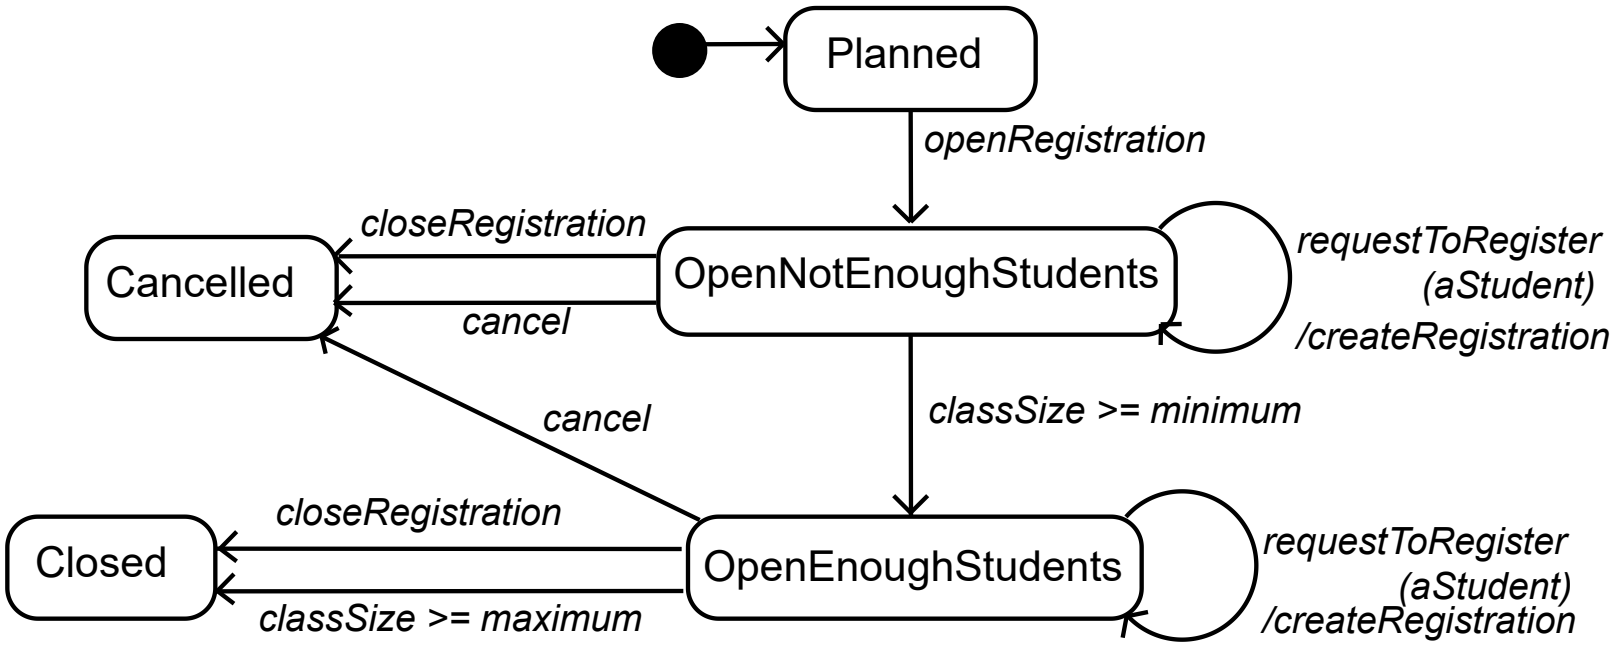
- A transition represents a change of state in response to an event.
  - It is considered to occur instantaneously.

- The label on each transition is the event that causes the change of state.

State diagrams – an example of transitions with time-outs and conditions



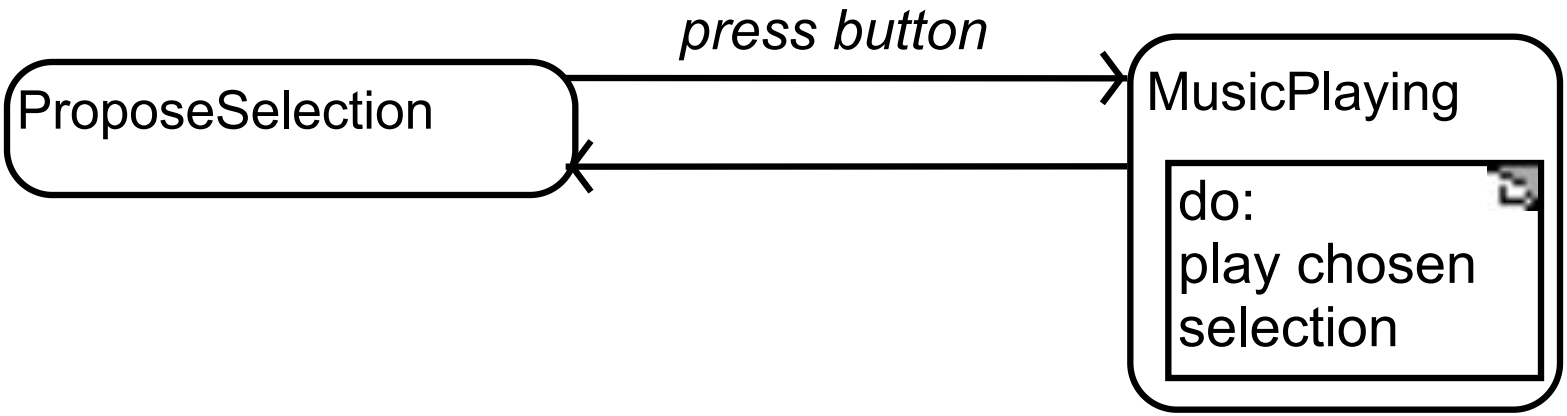
with conditional transitions



Activities in state diagrams

- An *activity* is something that takes place while the system is *in* a state.
  - It takes a period of time.
  - The system may take a transition out of the state in response to completion of the activity,
  - Some other outgoing transition may result in:
    - The interruption of the activity, and
    - An early exit from the state.

State diagram - an example with activity

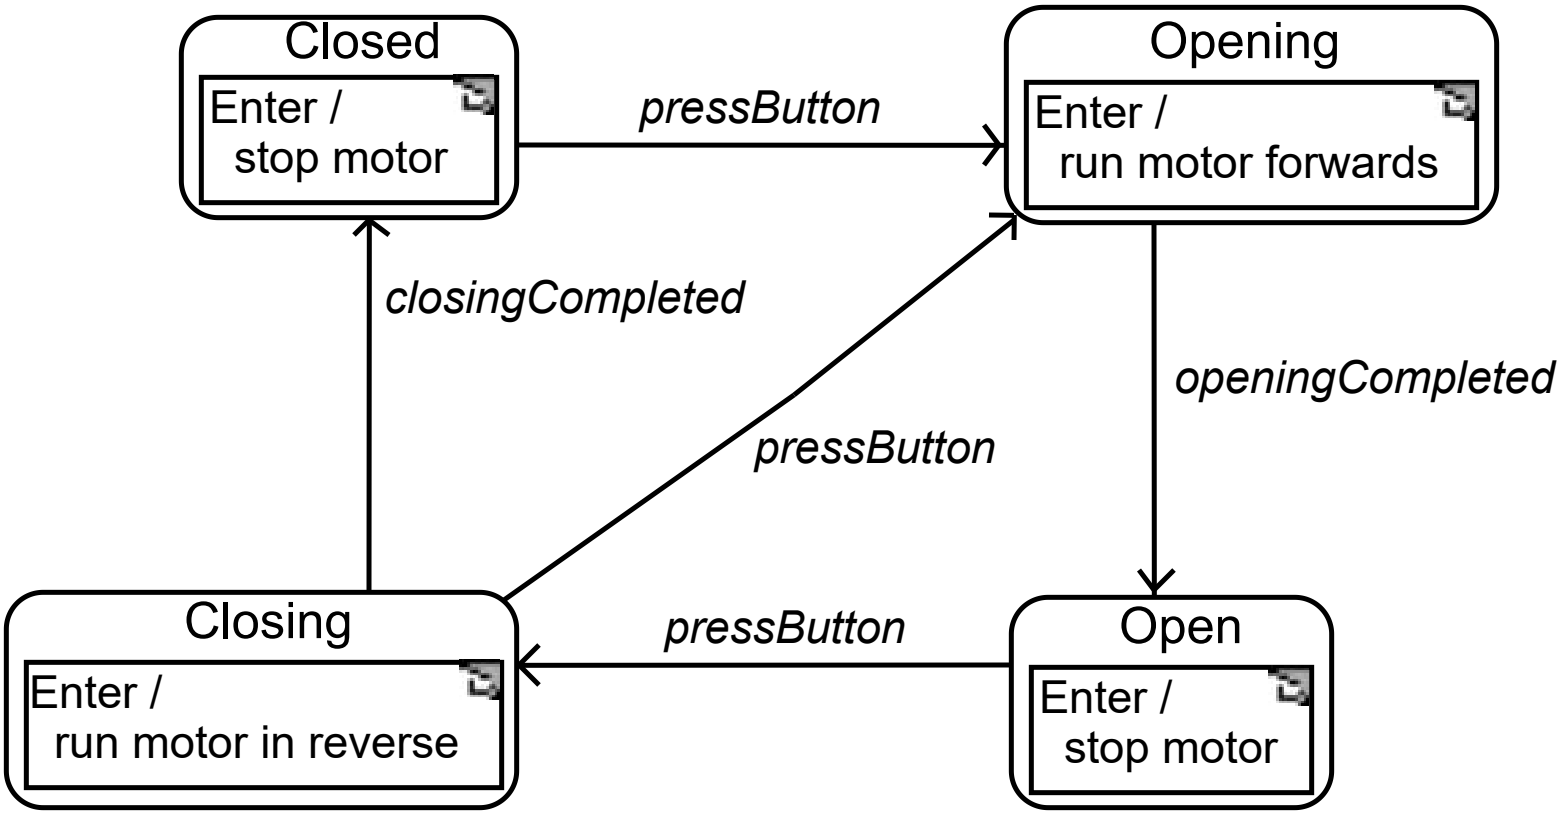


Actions in state diagrams

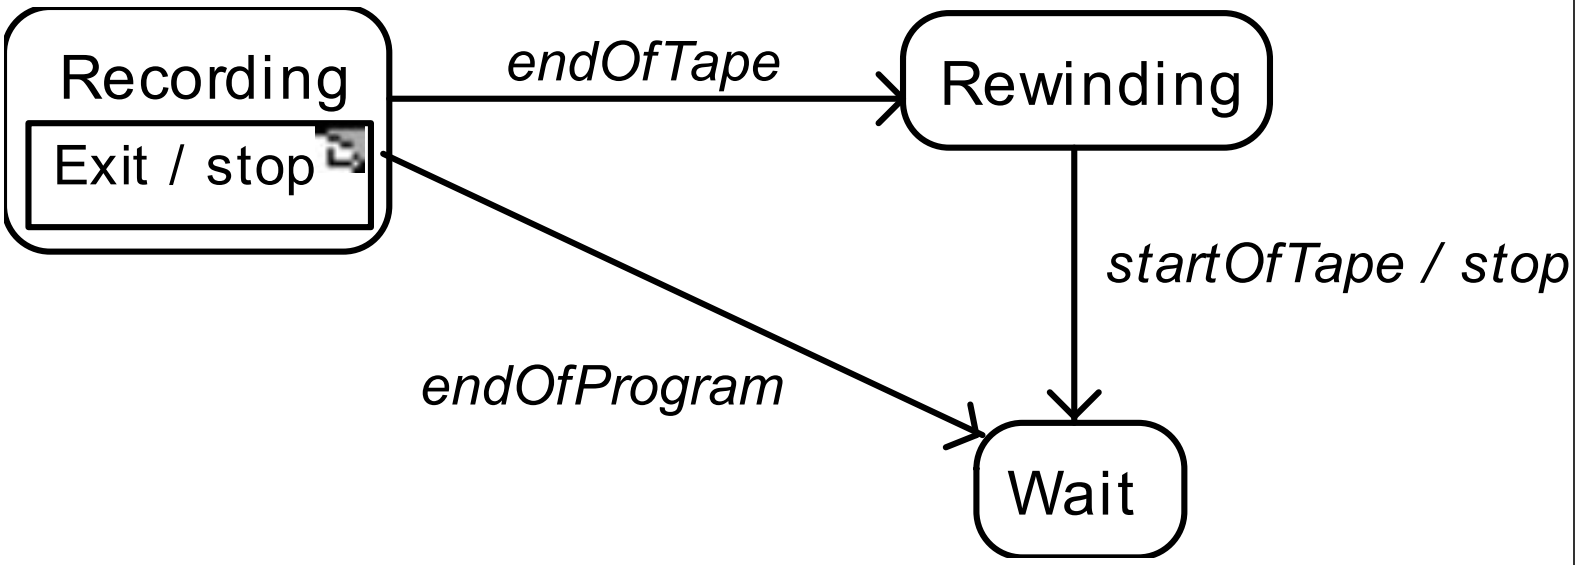
- An *action* is something that takes place effectively *instantaneously*
  - When a particular transition is taken,
  - Upon entry into a particular state, or
  - Upon exit from a particular state

- An action should consume no noticeable amount of time

State diagram – an example with actions

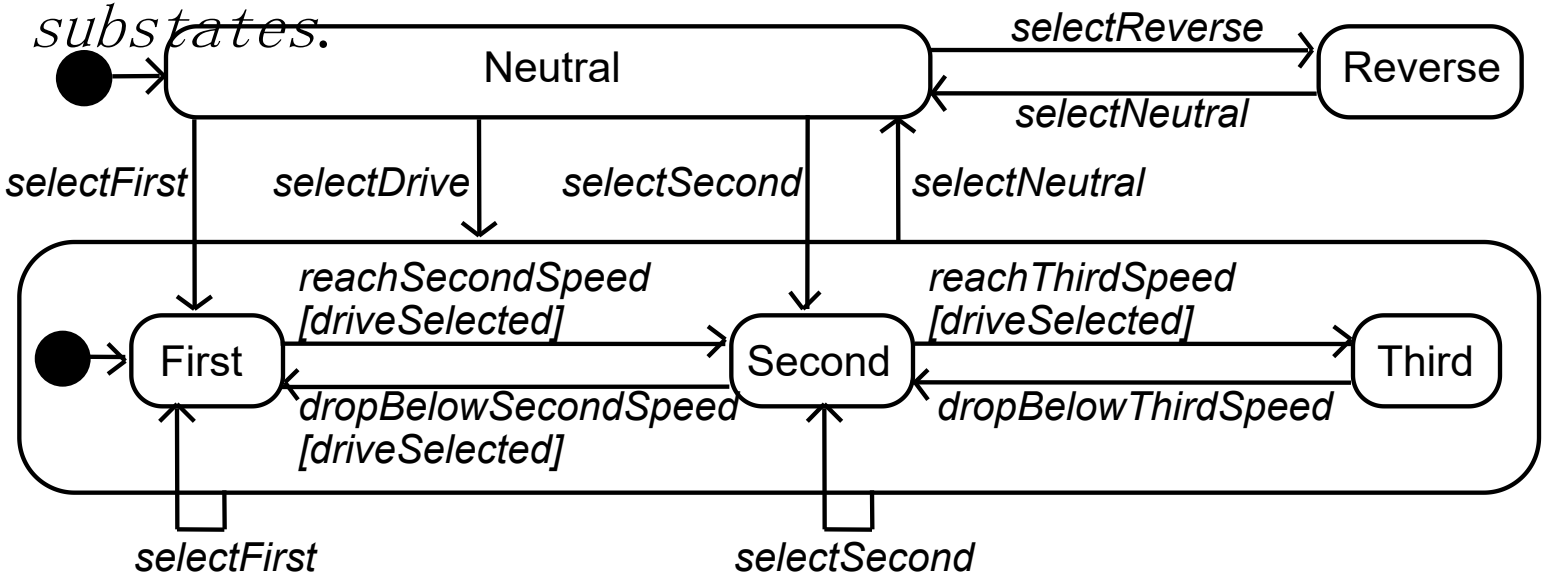


State diagrams - another example

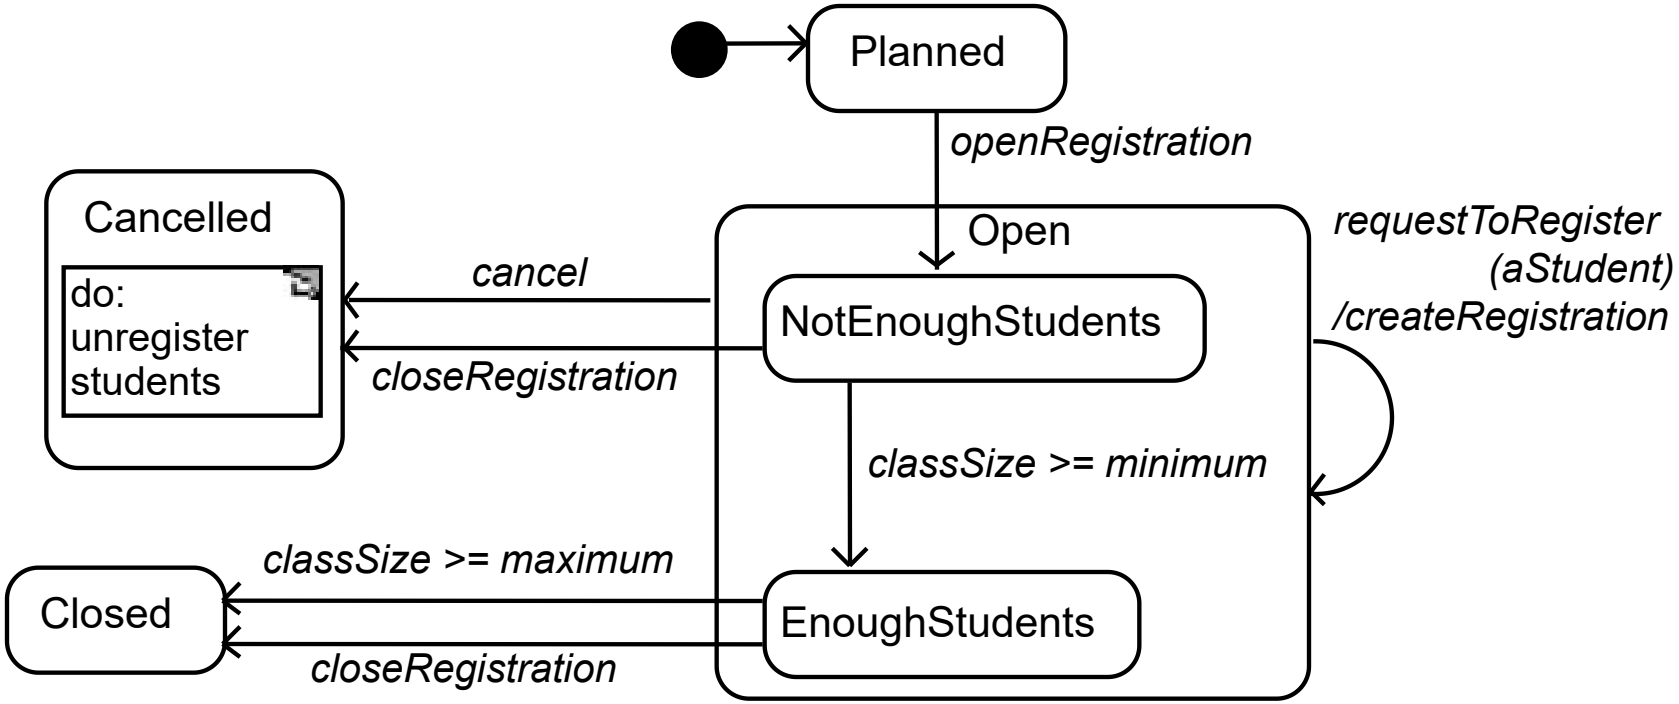


Nested substates and guard conditions

- A state diagram can be nested inside a state.
  - The states of the inner diagram are called *substates*.



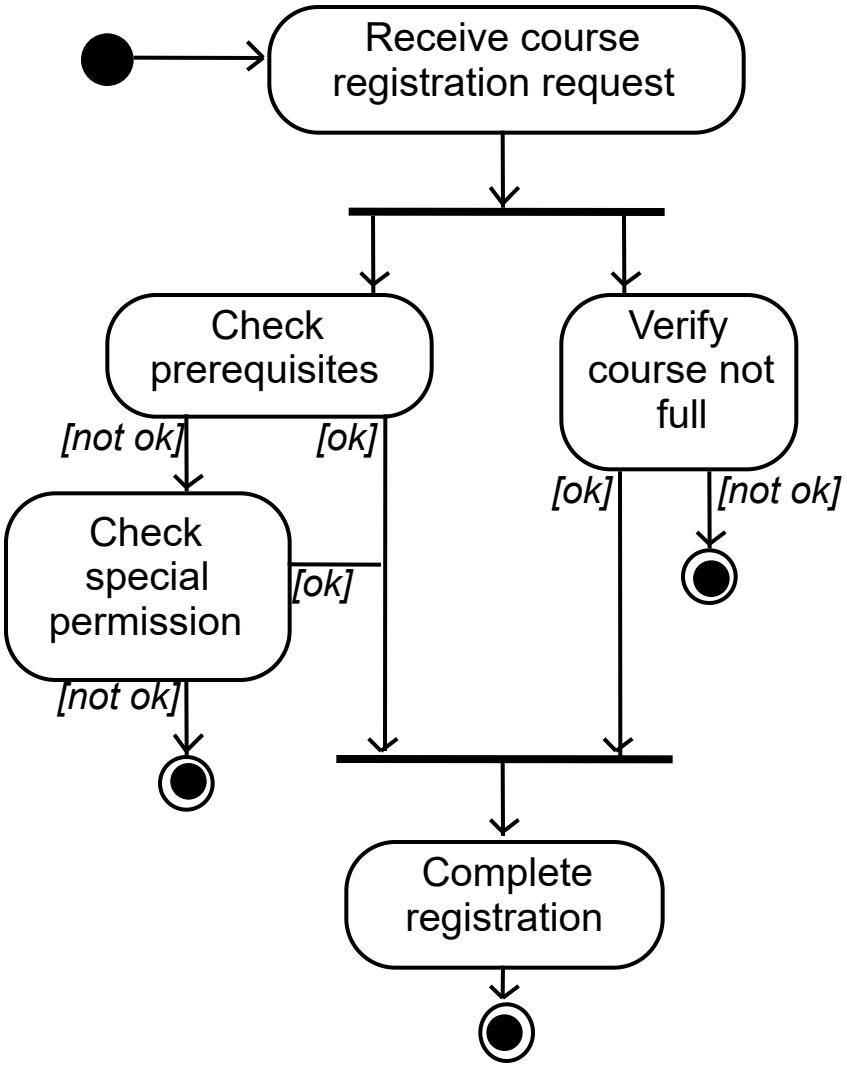
State diagram – an example with substates



Activity Diagrams

- An *activity diagram* is like a state diagram.
  - Except most transitions are caused by *internal* events, such as the completion of a computation.
- An activity diagram
  - Can be used to understand the flow of work that an object or component performs.
  - Can also be used to visualize the interrelation and interaction between different use cases.
  - Is most often associated with several classes.
- One of the strengths of activity diagrams is the representation of *concurrent* activities.

Activity diagrams - an example



Representing concurrency

- Concurrency is shown using forks, joins and rendezvous.
  - A *fork* has one incoming transition and multiple outgoing transitions.
    - The execution splits into two concurrent threads.
  - A *rendezvous* has multiple incoming and multiple outgoing transitions.
    - Once all the incoming transitions occur all the outgoing transitions may occur.

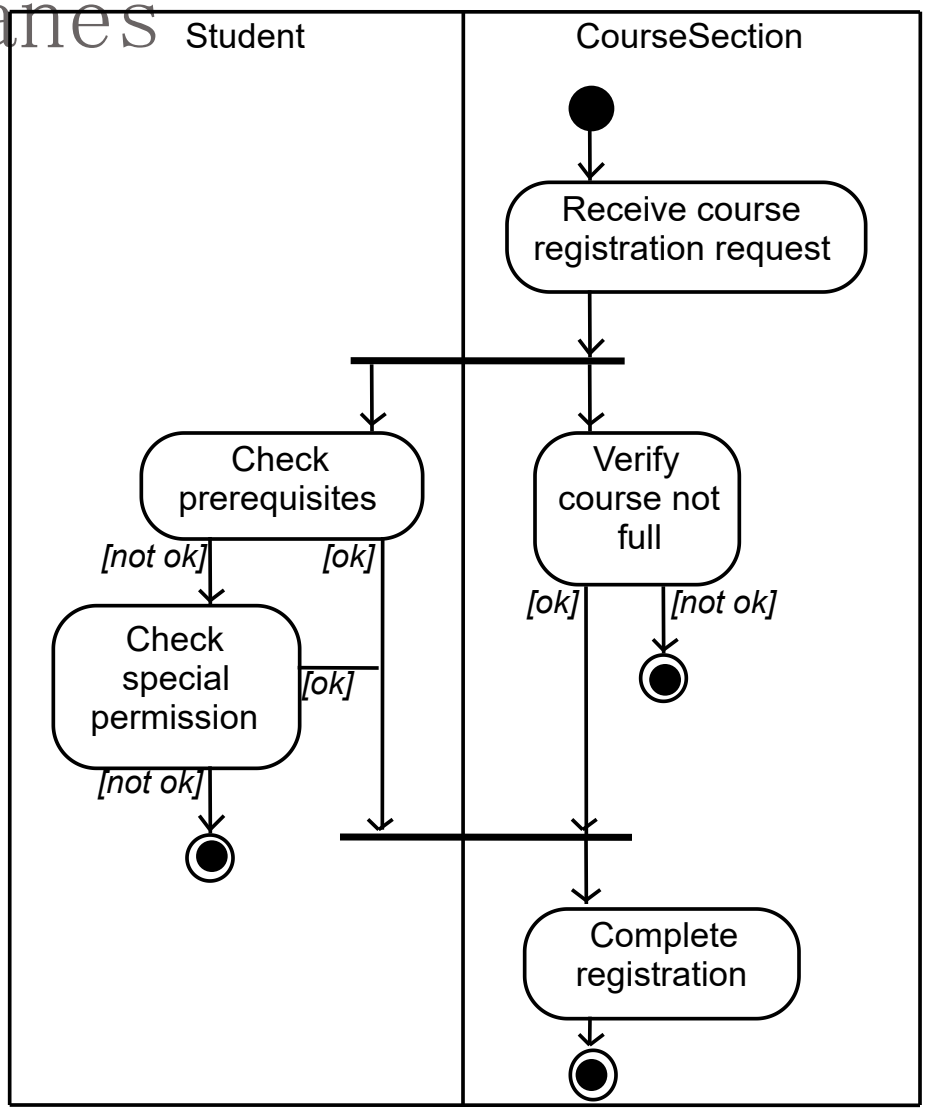
Representing concurrency

- A *join* has multiple incoming transitions and one outgoing transition.
  - The outgoing transition will be taken when all incoming transitions have occurred.
  - The incoming transitions must be triggered in separate threads.
  - If one incoming transition occurs, a wait condition occurs at the join until the other transitions occur.

Swimlanes

- Activity diagrams are most often associated with several classes.
  - The partition of activities among the existing classes can be explicitly shown using *swimlanes*.

Activity diagrams - an example with swimlanes



Interaction and State Diagrams

- You should use these diagrams for the parts of your system that you find most complex.
  - I.e. not for every class
- Interaction, activity and state diagrams help you create a correct implementation.
- This is particularly true when behaviour is *distributed* across several use cases.
  - E.g. a state diagram is useful when different conditions cause instances to respond differently to the same event.

Example: The **CourseSection** class

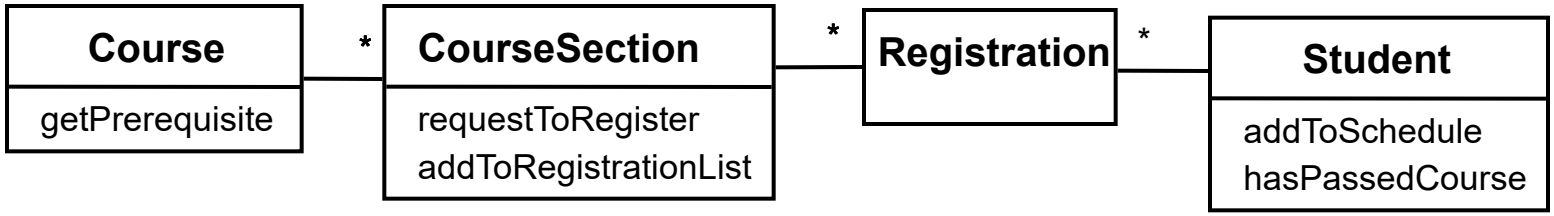
- States:
  - 'Planned':
    - **closedOrCancelled == false && open == false**
  - 'Cancelled':
    - **closedOrCancelled == true && registrationList.size() == 0**
  - 'Closed' (course section is too full, or being taught):
    - **closedOrCancelled == true && registrationList.size() > 0**

Example: The **CourseSection** class

- States:
  - 'Open' (accepting registrations):
    - **open == true**
  - 'NotEnoughStudents' (substate of 'Open'):
    - **open == true && registrationList.size() < course.getMinimum()**
  - 'EnoughStudents' (substate of 'Open'):
    - **open == true && registrationList.size() >= course.getMinimum()**

Example: The **CourseSection** class

- Class diagram



Example: The **CourseSection** class

```
public class CourseSection
{
  // The many-1 abstraction-occurence association
  private Course course;

  // The 1-many association to class Registration
  private List registationList;

  // The following are present only to determine
  // the state
  // The initial state is 'Planned'
  private boolean open = false;
  private boolean closedOrCancelled = false;
 ...
}
```

Example: The **CourseSection** class

```
public CourseSection(Course course)
{
  this.course = course;
  RegistrationList = new LinkedList();
}

public void cancel()
{
  // to 'Cancelled' state
  open = false;
  closedOrCancelled = true;
  unregisterStudents();
}
```

Example: The **CourseSection** class

```
public void openRegistration()
{
  if(!closedOrCancelled)
  // must be in ‘Planned’ state
  {
    open = true;
    // to 'OpenNotEnoughStudents' state
  }
}
```

Example: The **CourseSection** class

```
public void closeRegistration()
{
  // to 'Cancelled' or 'Closed' state
  open = false;
  closedOrCancelled = true;
  if (registrationList.size() <
    course.getMinimum())
  {
    unregisterStudents();
    // to ‘Cancelled’ state
  }
}
```

Example: The CourseSection class

```
public void requestToRegister(Student student)
  {
    if (open)  // must be in one of the two 'Open' states
    {
      // The interaction specified in the sequence diagram
      Course prereq = course.getPrerequisite();
      if (student.hasPassedCourse(prereq))
      {
         // Indirectly calls addToRegistrationList
         new Registration(this, student);
      }

      // Check for automatic transition to 'Closed' state
      if (registrationList.size() >= course.getMaximum())
      {
        // to 'Closed' state
        open = false;
        closedOrCancelled = true;
      }
    }
  }
```

Example: The **CourseSection** class

```
// Activity associated with 'Cancelled' state.
private void unregisterStudents()
{
  Iterator it = registrationList.iterator();
  while (it.hasNext())
  {
    Registration r = (Registration)it.next();
    r.unregisterStudent();
    it.remove();
  }
}

// Called within this package only, by the
// constructor of Registration
  void addToRegistrationList(
    Registration newRegistration)
  {
    registrationList.add(newRegistration);
  }
}
```

Difficulties and Risks in Modelling Interactions and Behaviour

- Dynamic modelling is a difficult skill
  - In a large system there are a very large number of possible paths a system can take.
  - It is hard to choose the classes to which to allocate each behaviour:
    - *Ensure that skilled developers lead the process, and ensure that all aspects of your models are properly reviewed.*
    - *Work iteratively:*
      - *Develop initial class diagrams, use cases, responsibilities, interaction diagrams and state diagrams;*
      - *Then go back and verify that all of these are consistent, modifying them as necessary.*
    - *Drawing different diagrams that capture related, but distinct, information will often highlight problems.*
